## UNCONSTRAINED & EQUALITY CONSTRAINED OPTIMIZATION

• Estimate the values of a and  $\theta$  that maximize the area from your plot. Does the maximum appear to be unique over the domain of physically-realistic values? Justify your answer.

The area of the trapezoidal cross-section is expressed as:

$$A(a, \theta) = \frac{1}{2} \left( (b + (b + a \times \cos(\theta))) \times h \right)$$
  

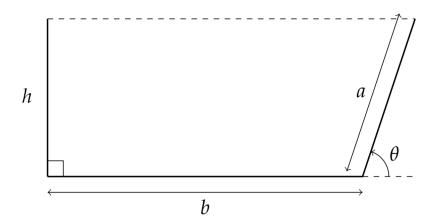

$$A(a, \theta) = \frac{1}{2} \left( (2 \times b + a \times \cos(\theta)) \times h \right)$$

we can write b and h as:

$$b = 3 - a \times (\sin(\theta) + 1)$$

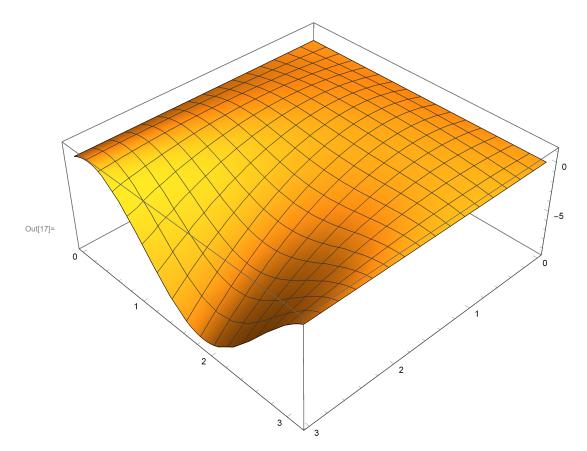

$$h = a \times \sin(\theta)$$

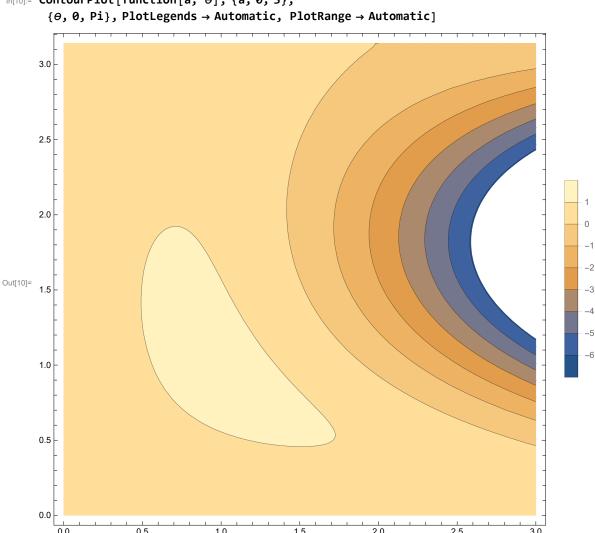

$$A(a, \theta) = \frac{1}{2} ((2 \times (3 - a \times (\sin(\theta) + 1)) + a \times \cos(\theta)) \times a \times \sin(\theta))$$

In[33]:= function [a\_, 
$$\theta$$
\_] :=  $\frac{1}{2}$  ((2 (3 - a (Sin[ $\theta$ ] + 1)) + a Cos[ $\theta$ ]) a Sin[ $\theta$ ])

 $\label{eq:local_local_problem} $$ \ln[17]:=$ Plot3D[function[a, \theta], \{a, 0, 3\}, \{\theta, 0, Pi\}, PlotRange \rightarrow Full] $$$ 

ln[10]:= ContourPlot[function[a,  $\theta$ ], {a, 0, 3},

To answer the question on the uniqueness of the maximum value of the function, we need to define the meaning of the physically-realistic values given the context of the problem.

The distances a and b have to be strictly positive but also strictly less than 3 since the constraint mentioned above states that the width of the metal sheet is W = 3 m. In other words, for a and b to exist, both of them have to be strictly greater than 0 and strictly smaller than 3.

The angle  $\theta$  has to be strictly greater than 0 and strictly smaller than  $\pi$  in order for the drainage channel to contain water. Failing to satisfy this constraint means that we can't physically hold water within the channel.

Under the above mentioned physically-realistic constraint, we can notice that the function has a estimated maximum of a little over 1  $m^2$  with values of a and  $\theta$  A(1, 1)

According to the contour plot, the maximum appears to be unique given the above mentioned constraint since there's no other region that has a contour value that exceeds 1 except of the yellow shaded area around  $A(\theta=1, a=1)$ 

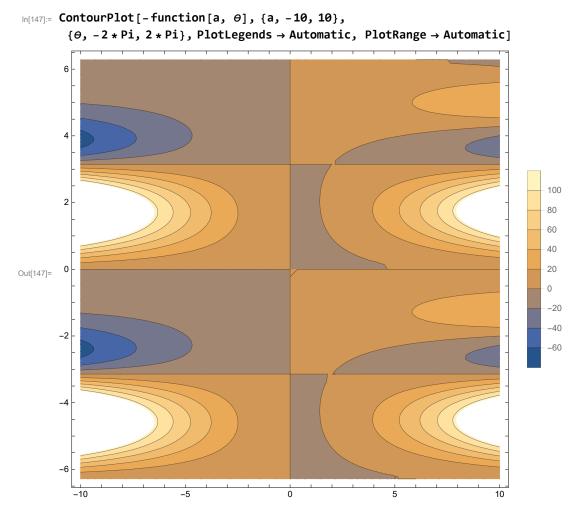

■ Determine whether or not the negated function  $-A(a, \theta)$  is coercive, justifying your answer.

The condition for a given function to be coercive is:

$$f$$
 is coercive if  $\lim_{\|x\|\to\infty} f(x) = \infty$ 

In other words, the output of the function f grows to infinity when the norm constructed by its variables tends towards infinity.

Below is the contour plot of the function  $-A(a,\theta)$ 

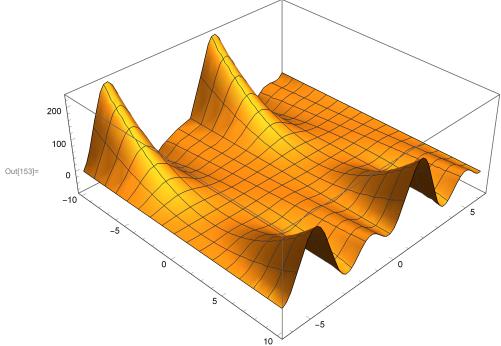

We know that the values of  $\theta$  when plugged into -A(a, $\theta$ ) will yield values between -1 and 1, thus, the parameter that might influence the growth of the function -A(a, $\theta$ ) is the length of the segment a. However, according to the contour plot, we can see that the function doesn't grow to infinity as we

increase the value a because the function depends also on the value of the angle  $\theta$  (see contour plot when  $\theta$ =4 on the y-axis).

As a result, even when not considering the physically-realistic values for a and  $\theta$ , the function -A(a, $\theta$ ) is not growing to infinity in all directions which implies that it's not coercive.

If we consider the physically-realistic constraints, then the sublevel sets of  $-A(a,\theta)$  would indeed be compact. But the the sets are not closed because boundary values are not included in the domain since the distance and the angle must be strictly greater than 0 and strictly less than 3 and  $\pi$  respectively. As a result, the negated function is not coercive. dom (A) =  $a \in (0, 3[, \theta \in (0, \pi[$ 

• Using multivariable calculus, find the exact values of a and  $\theta$  that maximize the cross-sectional area of the channel. To accomplish this, consider b as a variable and use Lagrange multipliers on the area function A(a, b,  $\theta$ ), constraining the three variables by the width of the sheet - this will simplify calculations compared to maximizing A(a,  $\theta$ ) directly. Prove that the solution you found maximizes the area by applying appropriate tests, assuming the domain is restricted to physically-realistic solutions

In[40]:= Simplify 
$$\left[\frac{1}{2}\left(\left(2 \times b + a \times \cos(\theta)\right) \times \left(a \times \sin(\theta)\right)\right)\right]$$
Out[40]:=  $\frac{1}{2}$  a  $\left(2b + a\cos[\theta]\right)$  Sin  $\left[\theta\right]$ 

Objective function:

$$\max A(a, b, \theta) = \frac{1}{2} ((2 \times b + a \times \cos(\theta)) \times (a \times \sin(\theta)))$$

Under the constraint:

$$a + b + a \times \sin(\theta) - 3 = 0$$

Introducing the Lagrangian Multiplier:

$$L(a, b, \theta, \lambda) = \frac{1}{2} ((2 \times b + a \times \cos(\theta)) \times (a \times \sin(\theta))) - \lambda(a + b + a\sin(\theta) - 3)$$

We take the gradient with respect of the variables:

$$\begin{aligned} & \ln[52] = \ \mathsf{L}\left[\mathsf{a}_{-}, \, \mathsf{b}_{-}, \, \vartheta_{-}, \, \lambda_{-}\right] \, := \, \frac{1}{2} \, \left( \left( 2 * \mathsf{b} + \mathsf{a} * \mathsf{Cos}\left[\vartheta\right] \right) \, \mathsf{a} * \, \mathsf{Sin}\left[\vartheta\right] \right) - \lambda \, \left( \mathsf{a} + \mathsf{b} + \mathsf{a} * \mathsf{Sin}\left[\vartheta\right] - 3 \right) \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}, \, \lambda_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}, \, \lambda_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}, \, \lambda_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}, \, \lambda_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}, \, \lambda_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}, \, \lambda_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \vartheta_{+}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}_{+}, \, \mathsf{b}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}\left[\mathsf{a}_{+}, \, \mathsf{b}\right], \, \mathsf{b}\right] \\ & \quad \mathsf{D}\left[\mathsf{L}$$

We then solve for the derivatives to be equal to zero:

Solve [D[L[a, b,  $\theta$ ,  $\lambda$ ], a] == 0, {a, b,  $\theta$ ,  $\lambda$ }, Reals]

Solve[D[L[a, b, 
$$\theta$$
,  $\lambda$ ], b] =  $\theta$ , {a, b,  $\theta$ ,  $\lambda$ }, Reals]  
Solve[D[L[a, b,  $\theta$ ,  $\lambda$ ],  $\theta$ ] =  $\theta$ , {a, b,  $\theta$ ,  $\lambda$ }, Reals]  
Solve[D[L[a, b,  $\theta$ ,  $\lambda$ ],  $\lambda$ ] =  $\theta$ , {a, b,  $\theta$ ,  $\lambda$ }, Reals]  
 $a=2$ ,  $b=1$ ,  $c=0$ ,  $x=2\pi n+\pi$ ,  $n\in\mathbb{Z}$   
 $a=6$ ,  $b=-3$ ,  $c=0$ ,  $x=2\pi n$ ,  $n\in\mathbb{Z}$   
 $a=4\sqrt{3}-6$ ,  $b=3-\sqrt{3}$ ,  $c=6-3\sqrt{3}$ ,  $x=2\pi n+\frac{\pi}{3}$ ,  $n\in\mathbb{Z}$ 

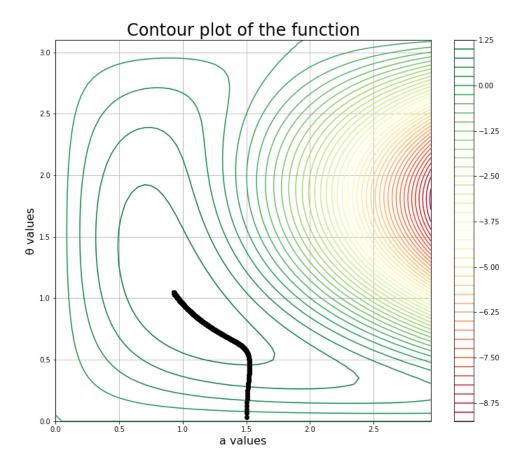

We can exclude the first solution since  $\theta$  can't be equal to  $\pi$ . Furthermore, The second solution appears to consider b as a negative metric which contradict with the physically-realistic assumptions. The last options seems to satisfy all constraint listed in part I, below is the numerical values of A(a,b, $\theta$ ),a,b, and  $\theta$ 

```
N[L[4Sqrt[3] - 6, 3 - Sqrt[3], Pi / 3, 6 - 3 Sqrt[3]]]
       N[4 Sqrt[3] - 6]
       N[3 - Sqrt[3]]
       N[Pi/3]
Out[123]= 1.20577
Out[124]= 0.928203
Out[125]= 1.26795
Out[126]= 1.0472
```

• Considering once again the function  $A(a, \theta)$ , implement gradient ascent with a line search (exact or backtracking) in Python and from the initial state (1.5, 0), verify that you reach the same optimal solution. Produce a table of steps showing how the algorithm converges, and plot the convergence over the contour plot of  $A(\cdot, \cdot)$ 

Using the NMaximizer function in Mathematica

```
log[*]:= NMaximize[{function[a, \theta], 0 < a < 3, 0 < \theta < Pi}, {a, \theta}]
      NMaximize \{function[a, \theta], 0 < a < 3, 0 < \theta < Pi, 3 - a <math>(Sin[\theta] + 1) > 0\}, \{a, \theta\}\}
\textit{Out[} \bullet \textit{]=} \quad \{\textbf{1.20577, } \{ \textbf{a} \rightarrow \textbf{0.928203, } \theta \rightarrow \textbf{1.0472} \} \}
\textit{Out[@]}= {1.20577, {a \rightarrow 0.928203, \theta \rightarrow 1.0472}}
